Abstract: Prediction of gender characteristics from iris images has been investigated and some successful results have been reported in the literature, but without considering performance for different iris features and classifiers. This paper investigates for the first time an approach to gender prediction from iris images using different types of features (including a small number of very simple geometric features, texture features and a combination of geometric and texture features) and a more versatile and intelligent classifier structure. Our proposed approaches can achieve gender prediction accuracies of up to 90% in the BioSecure Database.

1 INTRODUCTION

The estimation of soft-biometric characteristics of individuals based on extractable features of conventional biometric data has become a very important research topic. Biometric-based estimation of characteristics such as gender, age, and ethnicity is performed by using physical and/or behavioural characteristics embedded in an individual’s biometric data. This can be particularly useful in many practical scenarios (checking entitlement claims, for example) including, obviously, forensic investigations. In this paper, our focus is gender prediction from iris biometrics. The literature shows that face biometrics have received the greatest attention in relation to gender prediction [FD12]. This is perhaps not surprising since it is particularly natural and easy to obtain face images for applications such as criminal investigations or profiling from CCTV cameras. However, considerable effort has also been invested in estimating gender from other biometric modalities such as voice [Met07] and text [PDVV11] characteristics. On the other hand, if we consider the predictive properties of the iris in relation to gender characteristics of individuals, only two relevant reported studies [Tho07, LB11] can be found. Indeed, this is a potentially very challenging task, since gender information is not evident from direct human visual inspection of iris images.

In [Tho07], gender prediction is carried out using both geometric and texture features of iris images, and using bagging with the C4.5 decision tree classifier. This proposed gender prediction method was able to achieve 75% and 80% accuracy when tested respectively on the whole dataset and on a subset of this dataset corresponding only to Caucasian subjects. By contrast, in [LB11], gender prediction is carried out using only texture features of
iris images, but adopting a different type, and a larger number of texture features than in [Tho07] while using a support vector machine classifier. When tested on the whole dataset and on a subset corresponding only to single ethnicity subjects, this method was able to achieve an accuracy of around 62% in both cases. Possible reasons for this reduction in the attainable accuracy have been set out and explained in [LB11], summarised as follows:

- Differences in the dataset sizes: experiments in [Tho07] used over 28,000 images whereas in [LB11] 600 images were used, with a factor of around 50 difference in the training set size.
- Differences in the feature vectors: the results in [Tho07] are obtained with combined features computed on the log-Gabor filtered version of the iris image and geometric features, whereas in [LB11] features based on simple spot, line and Laws texture measures were used, without geometric features.
- Differences in the classification structure: the results in [Tho07] were obtained using a multiclassifier configuration (bagging 100 C4.5 decision tree [Qui93]), whereas results in [LB11] were obtained with a single classifier (support vector machine).

A proposed technique for gender prediction from iris samples was presented in [TPB15]. In this paper, once again, the authors use only iris texture and they claim up to 91% accuracy using a variation of fusion of uniform local binary patterns.

An analysis of ageing issues in iris biometrics [FE11] shows that physical ageing effects in iris samples are primarily the result of the physiology of pupil dilation mechanisms, with pupil dilation responsiveness decreasing with age. Hence, pupil dilation is very likely to be related to the geometric appearance of the pupil and the iris, where these findings suggest that geometric features of the iris may also provide useful information for the gender-based biometric prediction task.

Therefore, in this paper, we will investigate and explore the gender prediction task with respect to three different approaches which respectively use (a) only geometric features, (b) only texture features and (c) both geometric and texture features extracted from iris images, and we will use more versatile and intelligence-rich classification structures. We will compare achievable error-rate performance and execution times for each approach.

2 GENDER ESTIMATION USING IRIS IMAGES

The basic processing of biometric data in our iris-based gender prediction approach adopts a process based on the following: An eye image is captured in the Acquisition step. The Segmentation step localises the iris region from the acquired eye image. This step involves detection of the sclera/iris and pupil/iris boundaries. The Feature extraction step extracts geometric, texture or both geometric and texture features of the iris according to the configuration required. The Prediction step uses the data generated at the output of the previous step and performs the gender classification task itself.

224
The Data Set 2 (DS2) of the BioSecure Multimodal Database (BMDB) [OG10] is used in this study. The samples were collected as part of an extensive (and commercially available) multimodal database by 11 European institutions participating in the BioSecure Network of Excellence. The eye images were acquired in a standard “office” environment managed by a supervisor and using the LG Iris Access EOU3000 set-up. During the acquisition, spectacles were not allowed to be worn by subjects, although contact lenses were allowed. Four eye images (two left and two right) were acquired in two different sessions with a resolution of 640*480 pixels, for 210 subjects in total. However, the iris samples of 10 subjects were found to be incorrectly labelled in this database (some of the left eye samples labelled as right or vice versa), and were thus discarded. Hence, this decreased the available number of subjects to 200 (a total of 1600 images).

Using the defined iris dataset, each eye sample is first segmented using the automatic segmentation algorithm as described in [FE11, EF11]. In the event of segmentation failure (this occurred for only 1.87% of images), we segment the irises manually and make sure that all eye images are correctly segmented in order to guarantee the reliability of the further analysis. Subsequently, the obtained iris and pupil parameters from the segmentation process are stored for each eye, to be used in the further processing stages. A full description of these features can be found in [FE11, EF11].

2.0.1 Approach 1: Geometric feature extraction and correlation

By using the iris and the pupil parameters saved during the segmentation stage, several features which are related to the geometric characteristics of the iris are extracted. Here, it is important to note that the extraction of these features is computationally simple and fast, since none of them requires the extraction of texture information relating to the iris patterning.

The parameters which were obtained at the segmentation stage are: $p_x$ (which is the $x$-coordinate of the centre of the pupil), $i_x$ (which is the $x$-coordinate of the centre of the iris), $p_y$ (which is the $y$-coordinate of the centre of the pupil), $i_y$ (which is the $y$-coordinate of the centre of the iris), $i_r$ (which is the iris radius), and $p_r$ (which is the pupil radius). By using the pupil and iris parameters defined above, 12 (GF1-GF12) geometric features are extracted for our experimental study. Features GF1-GF7 were similarly defined and adopted as in [Tho07], while the remaining five features are specific to this study and adopted from [EFDCA13]. A brief description of these features (specified at the pixel level) is shown in Table 1.

Table 1: Geometric features

Then, a correlation evaluation across the features is carried out as in [EFDCA13]. By
removing the highly correlated features, efficiency is increased by adopting only the more
distinguishing and non-redundant features. The inter-feature correlations were evaluated
by using Spearman’s rank correlation (a nonparametric-based estimate of correlation).

2.0.2 Approach 2: Normalisation and texture feature extraction

After the segmentation stage, this approach performs a normalisation step. This step trans-
forms the iris region into a fixed rectangular block, so that the iris region extracted from
the overall eye image is presented at the fixed size necessary for comparisons between
samples. A technique [Mas03] based on Daugman’s rubber sheet model is employed,
which produces a 2D array with horizontal dimensions of angular resolution and vertical
dimensions of radial resolution. This produces an unwrapped image of size 20*240 pixels.
Following the normalisation, 1D Log-Gabor wavelets are used to encode features [Mas03].
Each row of the 2D normalised iris pattern corresponds to a circular ring on the iris region.
These rows are divided into a number of 1D signals and convolved with 1D Log-Gabor
wavelets which outputs a template of size 20*480 with both real and imaginary com-
ponents. As in [Tho07], we only use the real components (which correspond to the array
of complex numbers of size 20*240 of the template) to extract texture features, which are
defined in Table ?? . Features $TF_1$, $TF_2$, $TF_6$ were similarly defined and adopted in
[Tho07], while the remaining three features are specific to this study and adopted from
[EFDCA14].

2.0.3 Approach 3: Combining geometric and texture features

This approach simply adopts the combination of approach 1 and approach 2. Hence, ge-
ometric and texture features obtained from approach 1 and approach 2 respectively, are
combined simply by concatenating them.

2.1 Prediction

The gender prediction task involves the specification of how to form the training and test-
ing sets as well as the classification method to be applied. In order reliably to evaluate the
performance of the gender classification task, we divide the available samples into person-
disjoint testing and training sets. Thus, samples from approximately 72% of the male and
the female subjects are used as a training set and the remaining subjects’ samples are used
as a testing set.

One of the more difficult aspects of designing any classification task is making the best
choice of classifier or, in the case of a multiclassifier approach, choosing the set of base
classifiers for the fusion method. A guarantee of high diversity among the individual
components is essential in the latter context. In order to achieve diversity, we have se-
lected a pool of well known classifiers that have fundamentally different base structures for
this experimental study, named: Multi-Layer Perceptron (MLP) [Hay99], Support Vector
Machine (SVM) [FAE08], Optimised IREP (Incremental Reduced Error Pruning) (JRip) [FW94], Decision Tree (DT) [Qui93], K-Nearest Neighbour (KNN) [Ary98].

In order to analyse the full potential of using geometrical, texture and both geometrical and texture features, we have also considered a range of traditional fusion techniques and more intelligent combination techniques, named: Sum-based fusion (Sum) [KA03], Majority Voting (Vote) [Kun04] and Bagging [BB96]. We are especially interested in the use of intelligent agent-based architectures, which we have shown to be well suited to processing biometric data (see, for example, [DCAF11, AF09]). In this paper, we have chosen to analyse the performance of two different techniques, named: The Sensitivity-based Negotiation Method (Sens) and The Game Theory-based Negotiation Method (GT).

3 EXPERIMENTAL RESULTS AND DISCUSSION

In this section, we will present experimental results for the three approaches defined above, which are based on geometric (approach 1), texture (approach 2) and both geometric and texture (approach 3) features. We will analyse the proposed gender prediction approaches with respect to both the accuracy achieved and the execution time incurred at the classification stage, after the features were extracted and selected, using a Pentium IV computer with 2.40 GHz processor and 2048 MB RAM. The classifiers were implemented in Java.

For approach 1, all iris samples in the dataset are processed to form the biometric templates, passing through the steps of segmentation, geometric feature extraction and correlation as described in Section 2. Here, highly correlated features are designated as those with a correlation value greater than 0.4 (−0.4 ≤ ρ ≤ 0.4) as in [EFDCA13]. These features are discarded. The remaining uncorrelated 5 features (GF1 - GF4, and GF8) are used to form a feature vector for each iris sample in the dataset (with size of 1 * 5). For approach 2, all iris samples in the dataset are processed to form the biometric templates, passing through the steps of segmentation, normalisation and texture feature extraction as described in Section 2. Six texture-related features are used to form a feature vector for each iris sample in the dataset (with size of 1 * 780). For approach 3, the geometric and texture features from approach 1 and approach 2 are combined to form a feature vector for each iris sample in the dataset (with size of 1 * 785).

An initial experiment is performed to test the accuracy achieved and the execution time incurred at the classification stage of the proposed prediction approaches by using the defined feature vectors. The results are shown in Table 2.

Table 2: Accuracy (ACC) and execution time (ET) of individual classifiers
The results obtained show that approach 2 (texture features) achieves a better prediction accuracy rate than approach 1 (geometric features) with all classifiers (except the Jrip classifier) while approach 1 completes the classification stage with lower execution time than approach 2 with all classifiers. This suggests that texture features provide more useful information for the gender prediction task. The results also show that approach 3 achieves the best error-rate performance with all classifiers, but with the highest execution time. Of course, this result is not surprising, since approach 3 is the combination of approach 1 and approach 2 (i.e. adopts both geometric and texture features).

Considering these results further from the classification perspective, it is unsurprising to note that different classifiers return the best performance for different approaches, since they perform solution space search in different ways. However, it is very encouraging to see that these initial results for the process of gender prediction from iris images show that our approaches can outperform the systems previously described in the literature, where peak accuracy currently reported is typically around 75-80% [Tho07].

Hence, following these observations, and in order better to exploit the full potential of using the chosen geometrical and texture features, a second experiment is performed to investigate the attainable accuracy and execution time of the proposed gender prediction approaches when using the defined feature vectors with the combination-based classifiers presented in Section 2, with respect to the adopted dataset. The results obtained are shown in Table 3.

Table 3: Accuracy (ACC) and execution time (ET) of combined based classifiers

Thomas et al. [Tho07], reported around 80% accuracy by using a multiclassifier bagging with the C4.5 approach. In the work presented here, the proposed iris based gender prediction approach 1 uses only five simple geometric features of iris images and can reach accuracies close to 73% within approximately 2 seconds for classification (with the multiagent system using negotiation). Also our approach 3, which adopts both geometric and texture features as in [Tho07], is able to reach accuracies close to 90% within approximately 3 seconds using also the multiagent system.

4 CONCLUSION

In this paper we have investigated experimentally three approaches to gender prediction from iris images which use a combination of a small number of very simple (and therefore easily and efficiently computable) geometric features (ignoring texture-based information), or which uses texture features alone, or which uses both geometric and texture features.
features. By also adopting an intelligent classification structure, which we have previously found to be especially well suited to more conventional identity prediction from biometric data, we have developed a particularly effective gender prediction approach. Thus, our study has investigated how performance is influenced by the choice of the types of features used, and we have shown how implementing a more flexible and "intelligent" classification technique can support more efficient prediction using smaller number of features.

The performance we have been able to achieve - assigning each tested subject to one of two gender groups (corresponding to male and female categories) in relation to prediction accuracy, even with a small and limited feature set, is seen to be comparable to that reported elsewhere for the prediction of a gender determination problem, but which used a much larger and more diverse feature set. This comparative study based on different feature sets (i.e. geometric, texture and both geometric and texture features) and different classification approaches, provides valuable information to inform and guide the choice of feature and classification approaches in relation to particular application requirements.

This is a very positive outcome in a task domain which has been relatively little investigated to date. Although further work can still be carried out to improve and enhance the levels of achievable performance, our reported results show real promise in relation to the suitability of our basic techniques for application to a number of practical scenarios of importance and considerable current interest.
